
FOREST PRESERVE INVASIVE SPECIES WORK PLAN

Fiscal Year: 2025

Project # 381

Region: 5 and 6

Project Title: Work plan for *Phragmites australis* (Common reed grass) management on Forest Preserve in the Adirondack Park to be conducted by the Adirondack Park Invasive Plant Program (APIPP), hosted by the Nature Conservancy.

Species: *Phragmites australis* (Common reed grass)

Project Type: Standard

Short Environmental Assessment Form Part 1

Target Species Impacts and Concerns

Common reed grass is ranked very high (Relative Score = 92.00) under New York's Non-Native Plant Species Assessment Process. Areas impacted by common reed grass range from lake/pond edges to right-of-way shoulders of roads. Forested and emergent wetlands often provide the best conditions for invasion by this species. If infestations are not controlled, and suitable habitat is present, this species will spread vegetatively by rhizome growth and/or plant fragments to create a monotypic plant community in the impacted area. This can result in an overall decrease in the native biodiversity and ecological quality of the invaded habitat. Untreated infestations will continue to serve as source Clippopulations for future invasion. Due to the number of high-quality wetland ecosystems within the Adirondack Park, this species poses a very significant risk if left unaddressed.

Proposed Best Management Practices (BMPs)

Control Method - Foliar spray or clip and drip with glyphosate and/or imazapyr based herbicide

Herbicide Selected for Use – RoundUp Custom (EPA Reg. No. 524-343), Rodeo (EPA Reg. No. 62719-324), Accord XRT-II (EPA Reg. No. 62719-556), Arsenal Powerline (EPA Reg. No. 241-431) and/or Arsenal Applicators Concentrate (EPA Reg. No. 241-299)

Proposed Treatment Methods

Clip and drip – The clip and drip method will be used to treat stems that are within 3-feet of desirable native vegetation. This will create a “buffer zone” around desirable vegetation to reduce the likelihood for unintentional damage from subsequent foliar spray treatments. Clip and drip will also be used to create spray lanes through the interior of the infestation if the site is deemed too large or dense to be effectively treated by foliar spray from its exterior edge. Parallel spray lanes are cut through the heart of the infestation spaced 6-8 feet apart. Each stem that is cut to create the spray lanes will receive a clip and drip treatment with herbicide. Spay lanes allow the applicator easier access to the infestation and thereby promote better herbicide spray coverage and treatment efficacy. Clip and drip treatments will utilize 5ml of a 50% glyphosate solution, per the label recommendation.

Foliar Spray – The majority of the infestation will be treated via foliar spray with a 0.75% - 1.5% solution of glyphosate-based or 0.5% imazapyr-based herbicide, in accordance with label recommendations. A backpack or handheld sprayer will be used to administer a spray-to-wet application to the foliage of all untreated plants. The foliar spray method is useful in covering large or dense stands of vegetation efficiently but presents an increased likelihood for off-target impacts via herbicide spray drift. To reduce the chance of off-target impacts, foliar spray applications will be conducted during periods of little to no wind using an appropriate droplet size and spray pressure. A marking dye will be used to identify which plants have already been sprayed to prevent over application.

General Safety Procedures

Herbicide applications will follow all label precautions. Required and optional personal protective equipment will be available to staff at all times and utilized. All treatment areas will be adequately marked prior to control taking place.

Assessment of Treatment Alternatives

Cutting/Mulching – Cutting or mulching common reed grass is not recommended since plant fragments as small as 1 cm have the capability to re-sprout and form a new infestation.

Pulling/digging – Hand pulling and/or digging is usually not an option due to the size of the impacted area, the sites soil characteristics, and the number of plants present.

Herbicide – A treatment of glyphosate or imazapyr-based herbicide is currently the best option due to the size of the infestations and the effectiveness of the clip and drip and foliar spray methods.

Matting – Covering the site with black plastic is generally not an option due to the size of the infested area and/or the remoteness of the sites.

Excavation – This method is not currently a viable option due to its cost and/or the remoteness of the sites.

Timing and Priorities

Treatment Schedule - Treatments will be completed between July and September, when the plants are nearing full growth and flower, but at least three weeks before the first hard killing frost. At that time, the plants are actively transporting nutrients to their root system in preparation for winter dormancy. Treating during the flowering period helps facilitate the translocation of herbicide deeper into the plants root system resulting in a more effective treatment. All new infestations that establish in future years due to fragmentation, rhizomatic growth, or seed dispersal from these parent patches will be treated in a similar manner. Work will be considered complete when target invasive plants are no longer observed. At this point, sites will transition from the treatment phase to the monitoring phase as outlined in the *Monitoring Provisions* section below.

Treatment Priorities – These sites were prioritized for survey and treatment due to factors such as likelihood of spread, recent disturbance, proximity to streams, wetlands, sensitive habitats, and threatened species.

Natural Heritage Review

All sites were reviewed using the New York Natural Heritage datasets on rare, threatened, and endangered species. Reviews of the sites found most sites had no RTE species nearby these are

listed as NA. The only RTE species listed were loons and bald eagles and these species should not be impacted by our management.

Monitoring Provisions (Including the reporting of treatment to iMapInvasives)

Sites will be inspected annually for at least three years before being deemed eradicated of target species. If target species are detected during subsequent monitoring visits, follow-up treatment will be performed, and annual inspections will occur for at least three additional years. A photographic record and GPS data will be collected to document management progress of the site over time, with all monitoring and treatment data uploaded to iMapInvasives.

APA General Permit 2014G-1B

Certification to Use General Permit
2014G-1B to Manage Terrestrial Invasive
Species in or Potentially Impacting
Wetlands in the Adirondack Park

Issued to: APIPP

This certifies that the above-named Authorized User is included on the Adirondack Park Agency's Authorized Users List of Agency General Permit 2014G-1B for the management of terrestrial invasive species in or potentially impacting wetlands in the Adirondack Park.

The qualified representative for the Authorized User is responsible for ensuring that all of the conditions listed in APA General Permit 2014G-1B are complied with. This includes submission of an annual report, due by February 28th of the following year, summarizing the activities undertaken by the Authorized User pursuant to Condition 11 of Agency General Permit 2014G-1B.

The Deputy Director of Regulatory Programs (DDRP) maintains a list of persons approved to use GP2014G-1B. Authorized Users will remain eligible to use GP2014G-1B unless deemed to not be in compliance with the conditions listed in GP2014G-1B. Authorized users may be removed from the list at the discretion of and upon notification by the DDRP.
